

Why Do Naive SFT Filters For Safety Properties Fail?

By: AI Alignment Forum

Source: AI Alignment Forum

What's New

****Claim****

Naive SFT data filtering is ineffective at removing undesirable safety properties from language model outputs.

****Evidence****

The post presents empirical findings showing that filtering does not significantly improve safety outcomes in the examined rollouts. Specific experiments and model comparisons reveal that undesirable properties persist despite filtering efforts, suggesting a systematic issue with this approach.

****Method****

The research involved analyzing outputs from language models trained with supervised fine-tuning (SFT) and applying various filtering techniques to assess their impact on safety properties. The evaluation setup focused on identifying the presence of undesirable characteristics in the filtered outputs.

****Limitations****

The analysis may be limited in scope, as it primarily addresses specific filtering techniques without exploring alternative strategies. Additionally, the reproducibility of results could be affected by the selection of models and datasets used in the study.

****Safety relevance****

These findings highlight the challenges in ensuring safety in AI systems, emphasizing the need for more robust and effective filtering strategies in alignment efforts.
