

Endogenous Alignment

By: AI Alignment Forum

Source: AI Alignment Forum

What's New

****Claim****

Adults use exogenous methods to align children's behavior with societal values from a very young age.

****Evidence****

The description indicates that this alignment begins around the age of one, employing operant conditioning through rewards and punishments. However, specific empirical studies or data supporting the effectiveness of these methods are not provided.

****Method****

The work is framed conceptually rather than based on empirical analysis, focusing on behavioral conditioning techniques rather than experimental validation.

****Limitations****

The claims lack empirical backing and do not provide specific studies or data, which raises questions about the generalizability and applicability of the findings. Additionally, the focus on conditioning may oversimplify the complexities of human value alignment.

****Safety relevance****

Understanding the mechanisms of alignment in early development could inform approaches to align AI systems with human values, though caution is warranted given the limited evidence presented.
