

Value generalisation: value correction

By: AI Alignment Forum

Source: AI Alignment Forum

What's New

****Claim****

Value generalisation is essential for AI alignment, specifically through the mechanism of value correction in reinforcement learning agents.

****Evidence****

The author presents an example of an RL agent that identifies and corrects its reward function based on human feedback. Specific empirical results or quantitative metrics supporting the effectiveness of this value correction mechanism are not provided in the summary.

****Method****

The discussion centers around a reinforcement learning framework where agents learn from human demonstrations to adjust their reward functions. However, no specific datasets or experimental setups are detailed.

****Limitations****

The concept of value generalisation may be overly broad and lacks thorough empirical validation in diverse scenarios. Additionally, the example provided does not account for potential confounding factors in real-world applications.

****Safety relevance****

The insights into value correction inform the design of alignment strategies that enable AI systems to better understand and adjust to human values.
